## Multi-agent Reinforcement Learning (MARL)

#### MARL Problem

The MARL problem involves finding policies for multiple robots to maximize the expected future rewards.

The objective is to derive a policy parameter  $\theta_i (i = 1, \dots, N)$  that maximizes the expected cumulative reward for robot i:

$$J(\theta_i) = E\left[\sum_{k=0}^{\infty} \gamma^k r_i(t+k)\right]$$
 (1)

where  $r_i$  is immediate reward, and  $\gamma$  ( $0 < \gamma \le 1$ ) is a discount factor that determines how much future rewards are discounted compared to the immediate reward.

#### Value Function

**State-action value function** Q(s, a): The expected cumulative reward obtained by taking a specific action a in state s

$$Q(s,a) = E\left[\sum_{k=0}^{\infty} \gamma^k r(t+k)|s,a\right]$$
 (2)

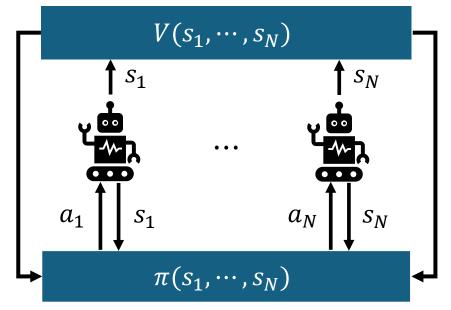

**State value function** V(s): The expected cumulative reward in state s

$$V(s) = E\left[\sum_{k=0}^{\infty} \gamma^k r(t+k)|s\right]$$
 (3)

Both value functions are utilized to evaluate and improve the policy.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 7/35

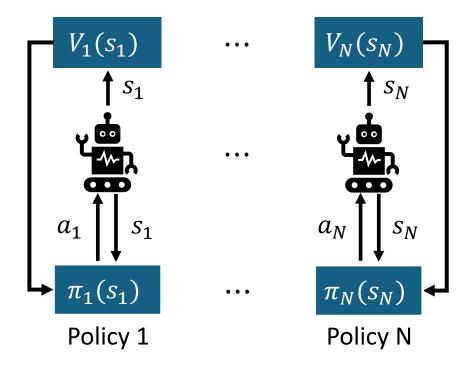

#### MARL Approaches

Central policy in Server

#### **Centralized Training**

- ✓ Stable training owing to full observation
- X Unapplicable if the central policy stops

#### **Decentralized Training**

- ✓ Applicable without the central policy
- X Unstable training due to partial observation

How can we utilize the advantages of both approaches?

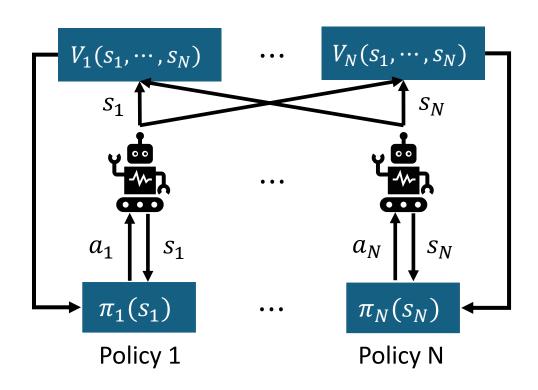

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 8/35

## Centralized Training and Decentralized Execution (CTDE)

#### **Centralized Training**

 To utilize the states and actions of all robots during training phase

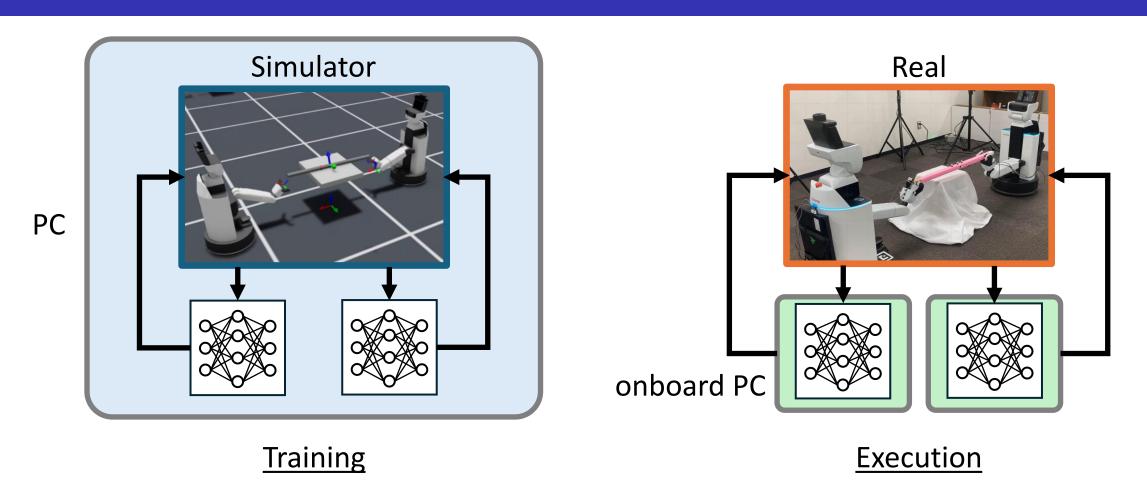

#### **Decentralized Execution**

 To utilize the state of each robot during execution phase

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 10/35

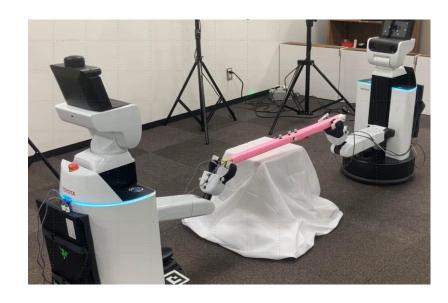

## CTDE and Robot Learning

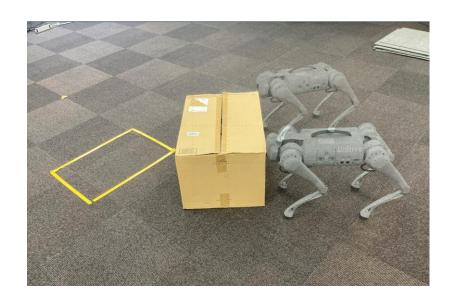

If we conduct training in a simulator, we can utilize information about other robots. In the real experiment, the robot computes action using its own observation.

## Exercise 5-1: MARL to Robot Application

- 1. Consider issues when applying MARL to real robot tasks.
- 2. Consider ideas for solving above issues.
- You now have about 8 minutes to write up your report
- Write your name and student number in your report

## Multi-agent Deterministic Policy Gradient (MADDPG)

Let's confirm how to update these networks.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 14/35

## Policy Update

The objective of MADDPG is to derive a policy that maximizes the following objective function:

$$J(\theta_i) = E[Q_i(s, a)] \tag{4}$$

where  $s \coloneqq [s_1, \dots, s_N]$  is joint state of N robots,  $a \coloneqq [a_1, \dots, a_N]$  is joint action of N robots.

By taking the gradient w.r.t  $\theta_i$ , we obtain:

$$\nabla_{\theta_i} J(\theta_i) = E[\nabla_{\theta_i} Q_i(s, a)] \tag{5}$$

Using the chain rule, this can be further expanded as:

$$\nabla_{\theta_i} J(\theta_i) = E \left[ \nabla_{\theta_i} \pi_{\theta_i}(s_i) \nabla_{a_i} Q_i(s, a) \right] \tag{6}$$

This decomposition allows the gradients of the policy and the value function to be computed separately, making the gradient calculations simpler.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 15/35

#### con't

Next, we consider updating the weight parameter of the actor network  $\theta_i$ .

Using the gradient  $\nabla_{\theta_i} J(\theta_i)$ ,  $\theta_i$  is updated as follows:

$$\theta_i \leftarrow \theta_i + \alpha \nabla_{\theta_i} J(\theta_i) \tag{7}$$

where  $\alpha > 0$  is the learning rate.

To ensure stable learning, MADDPG utilizes the target network to update the network gradually.

The target network parameters are updated as follows:

$$\theta_i' \leftarrow \tau \theta_i + (1 - \tau)\theta_i' \tag{8}$$

where  $\theta_i'$  is the weight parameter of target network, and  $\tau(0 < \tau \ll 1)$  controls the update rate.

The use of the target network stabilizes training by introducing a first-order time-delay system.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 16/35

## Value Function Update

Next, we consider updating the value function.

State-action value function is written in recursive form:

$$Q_i(s,a) = E\left[r_i(t) + \gamma \sum_{k=0}^{\infty} \gamma^k r_i(t+k+1)|s,a\right]$$
(9)

Using the law of total expectation E[X] = E[E[X|Y]], the Bellman equation for the state-action value function can be derived as:

$$Q_{i}(s,a) = E\left[r_{i}(t) + \gamma E\left[\sum_{k=0}^{\infty} \gamma^{k} r_{i}(t+k+1) \middle| s', a'\right] \middle| s, a\right]$$

$$= E[r_{i}(t) + \gamma Q_{i}(s', a')]$$

$$(10)$$

$$= E[r_{i}(t) + \gamma Q_{i}(s', a')]$$

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 17/35

#### con't

Define a target value function  $y_i$  as follows:

$$y_i = r_i(t) + \gamma Q_i(s', a') \tag{12}$$

The objective is to train the critic network to bring the predicted  $Q_i(s, a)$  closer to  $y_i$ .

This can be achieved by minimizing the following loss function:

$$L(\phi_i) = E\left[ \left( y_i - Q_i(s, a) \right)^2 \right] \tag{13}$$

The weight parameter of the critic network  $\phi_i$  is updated as follows:

$$\phi_i \leftarrow \phi_i - \beta \nabla_{\phi_i} L(\phi_i) \tag{14}$$

Similarly, the critic network is updated using a target network to ensure stable learning:

$$\phi_i' \leftarrow \tau \phi_i + (1 - \tau)\phi_i' \tag{15}$$

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 18/35

## Experience Replay: How to utilize the experience data?

MADDPG implements experience replay, which utilizes past experiences stored in a replay buffer:

$$D = \{(s, a, s', r)\}\tag{16}$$

To train efficiently and stably from past experiences, a mini-batch B, a small random subset of experiences, is sampled from D.

Using the mini-batch, the policy gradient is computed as:

$$\nabla_{\theta_i} J(\theta_i) \approx \frac{1}{|B|} \sum_{(s,a,s',r) \sim B} \nabla_{\theta_i} \pi_{\theta_i}(s_i) \nabla_{a_i} Q_i(s,a)$$
(17)

Similarly, the critic loss function is computed as:

$$L(\phi_i) \approx \frac{1}{|B|} \sum_{(s,a,s',r) \sim B} \left( y_i - Q_i(s,a) \right)^2 \tag{18}$$

# Simulation: Position Control using MADDPG

#### Objective: To control the positions of two agents to the goal positions

• State  $s_i$ 

$$s_i = p_i \tag{19}$$

 $p_i$ : Position of agent i

• Action  $a_i$ 

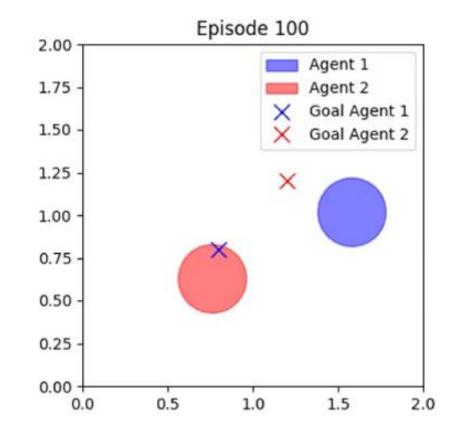

$$a_i = u_i \tag{20}$$

 $u_i$ : Velocity input of agent i

• Reward  $r_i$ 

$$r_i = -|g_i - p_i| \tag{21}$$

 $g_i$ : Goal position of agent i

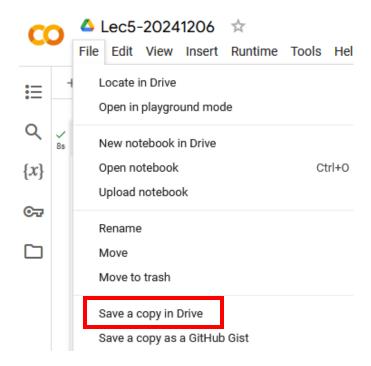

## How to use the Google Colab

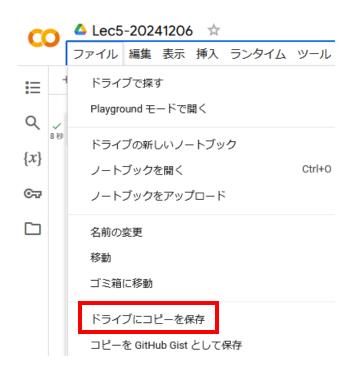

1. Access Google Colab through the URL below

https://colab.research.google.com/drive/1JnRMb3haAvYW9eTZAwOCcDVwKQGlVc-

0?usp=sharing

2. Save to your Google Drive

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 21/35

#### Exercise 5-2: MADDPG

Please design the observation and reward so that each agent can reach the goal position while reducing the number of collisions.

#### Please try following steps:

1. Add the collision penalty

```
collision_penalty = 0 if distance_between_agents < 2 * agent_radius else 0
```

- 2. Add the state of the other agent
- You have 20 min to implement your code
- If you have any trouble, please feel free to ask.

#### **Table of Contents**

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 23/35

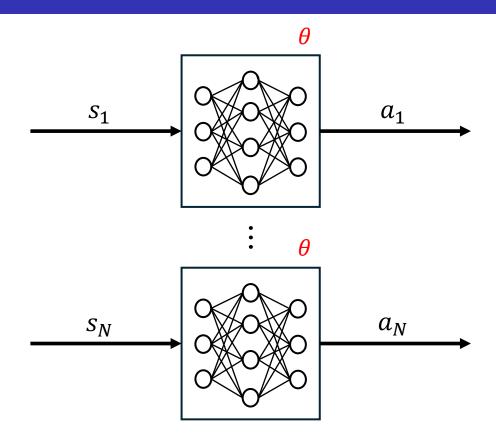

## Multi-agent Proximal Policy Optimization (MAPPO)

#### **Parameter sharing**

Sharing the same parameter for all agents can improve the learning efficiency.

Critic Network (= Value Function)

Actor Network (= Policy)

Let's confirm how to update these networks.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 24/35

## Advantage Function

The advantage function A(s, a) measures how much a specific action a outperforms the average action in state s. It is defined as:

$$A(s,a) \coloneqq Q(s,a) - V(s) \tag{22}$$

Let's consider following cases.

- A(s,a) > 0: Action a is better than the average action in state s.
- A(s,a) < 0: Action a is worse than the average action in state s.

Maximizing the advantage function A(s,a) ensures that the policy selects action that outperforms the average action, thereby improving the policy.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 25/35

## Policy Update

MAPPO aims to maximize the following objective function:

$$J(\theta) = \sum_{i=1}^{N} E[A(s_i, a_i)] = \sum_{i=1}^{N} \int \pi_{\theta}(a_i | s_i) A(s_i, a_i) ds da$$
 (23)

Take the derivative of  $J(\theta)$  w.r.t  $\theta$ , we obtain:

$$\nabla_{\theta} J(\theta) = \sum_{i=1}^{N} \int \nabla_{\theta} \pi_{\theta}(a_i | s_i) A(s_i, a_i) ds da$$
 (24)

In MAPPO, the policy ratio is used to measure how much the current policy outperforms the previous policy as follows:

$$\nabla_{\theta} J(\theta) = \sum_{i=1}^{N} \int \nabla_{\theta} \pi_{\theta_{\text{old}}}(a_i | s_i) \frac{\pi_{\theta}(a_i | s_i)}{\pi_{\theta_{\text{old}}}(a_i | s_i)} A(s_i, a_i) ds da$$
 (25)

MAPPO maximizes the following objective function:

$$L(\theta) = \sum_{i=1}^{N} E\left[\frac{\pi_{\theta}(a_i|s_i)}{\pi_{\theta_{\text{old}}}(a_i|s_i)} A(s_i, a_i)\right]$$
(26)

To ensure the stability of training, MAPPO employs a clipped objective:

$$L^{\text{CLIP}}(\theta) = \sum_{i=1}^{N} E\left[\min\left(\frac{\pi_{\theta}(a_i|s_i)}{\pi_{\theta_{\text{old}}}(a_i|s_i)}A(s_i, a_i), \operatorname{clip}\left(\frac{\pi_{\theta}(a_i|s_i)}{\pi_{\theta_{\text{old}}}(a_i|s_i)}, 1 - \epsilon, 1 + \epsilon\right)A(s_i, a_i)\right)\right]$$
(27)

The clip function is defined as:

$$\operatorname{clip}(x, 1 - \epsilon, 1 + \epsilon) = \begin{cases} x, & \text{if } 1 - \epsilon < x < 1 + \epsilon \\ 1 - \epsilon, & \text{if } x < 1 - \epsilon \\ 1 - \epsilon, & \text{if } x > 1 + \epsilon \end{cases}$$
 (28)

The weight parameter of the actor network is updated as follows:

$$\theta \leftarrow \theta + \alpha \nabla_{\theta} L^{\text{CLIP}}(\theta) \tag{29}$$

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 27/35

## Value Function Update

Next, we consider updating the state value function  $V(s_i)$ .

State value function is written in recursive form:

$$V(s_i) = E\left[r_i(t) + \gamma \sum_{k=0}^{\infty} \gamma^k r_i(t+k+1) \middle| s_i\right]$$
(30)

Using the law of total expectation E[X] = E[E[X|Y]], the Bellman equation for the state value

function can be derived as:

$$V(s_i) = E\left[r_i(t) + \gamma E\left[\sum_{k=0}^{\infty} \gamma^k r_i(t+k+1) \middle| s_i'\right] \middle| s_i\right]$$
(31)

 $= E[r_i(t) + \gamma V(s_i')] \tag{32}$ 

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 28/35

#### con't

Define a target value function  $y_i$  as follows:

$$y_i = r_i + \gamma V(s_i') \tag{33}$$

The objective is to learn the critic network so that the predicted value can get closer to  $y_i$ .

This can be achieved by minimizing the following loss function:

$$L(\phi) = E\left[\left(y_i - V(s_i)\right)^2\right] \tag{34}$$

Similarly, clipping is used to prevent the state value function from changing abruptly.

$$L^{\text{CLIP}}(\phi) = \sum_{i=1}^{N} E\left[\max\left([(V(s_i) - y_i)^2], (\text{clip}(V(s_i), V_{\text{old}}(s_i) - \epsilon, V_{\text{old}}(s_i) + \epsilon) - y_i)^2\right)\right]$$
(35)

The weight parameter of the critic network is updated as follows:

$$\phi \leftarrow \phi - \beta \nabla_{\phi} L^{\text{CLIP}}(\phi) \tag{36}$$

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 29/35

## Generalized Advantage Estimator (GAE)

The advantage function can be computed using the Bellman equation as:

$$A(s_i, a_i) = E[r_i(t) + \gamma V(s_i')] - V(s_i)$$
(37)

Define the TD Error

$$\delta_i(t) = r_i(t) + \gamma V(s_i') - V(s_i) \tag{38}$$

Using  $\delta_i(t)$ , the advantage function can be written as:

$$A(s_i, a_i) = E\left[\sum_{l=0}^{\infty} \gamma^l \delta_i(t+l)\right]$$
(39)

The GAE introduces a weight parameter  $\lambda$  (0 <  $\lambda$   $\leq$  1)

$$A(s_i, a_i) = E\left[\sum_{l=0}^{\infty} (\gamma \lambda)^l \delta_i(t+l)\right]$$
 (40)

where  $\lambda$  is used to reduce the influence of future TD errors, which stabilizes the training.

Kazuki Shibata (NAIST) Robot Learning and Control Dec. 6, 2024 30/35

#### Exercise 5-3: GAE

Derive

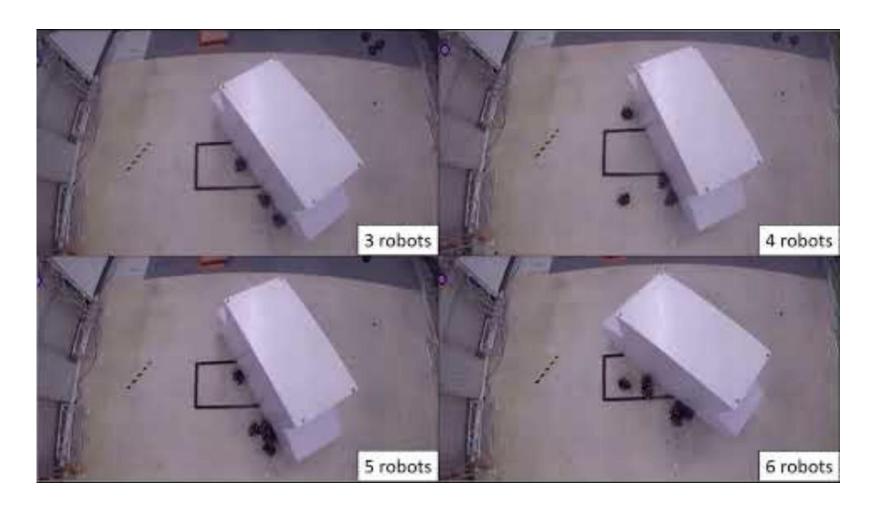

$$A(s_i, a_i) = E\left[\sum_{l=0}^{\infty} \gamma^l \delta_i(t+l)\right]$$

using the following formula:

$$A(s_i, a_i) = E[r_i(t) + \gamma V(s_i')] - V(s_i)$$
  
$$\delta_i(t) = r_i(t) + \gamma V(s_i') - V(s_i)$$

You now have about 8 minutes to write up your report
